INTRODUCTION

1.1 OVERVIEW

Music genre is a conventional category that identifies some pieces of music as belonging to a shared tradition or set of conventions. It is to be distinguished from musical form and musical style, although in practice these terms are sometimes used interchangeably Automatic musical genre classification can assist humans or even replace them in this process and would be of a very valuable addition to music information retrieval systems. Dividing music into genres is arbitrary, but there are perceptual criteria that are related to instrumentation, structure of the rhythm and texture of the music that can play a role in characterizing particular genre.

1.2 PURPOSE

The goal of this project is to build a proof-of-concept music genre classifier using a deep learning approach that can correctly predict the genre and confidence level of Western music from four candidate genres (classical, jazz, rap, rock,etc).

In this music genre classification project, we have developed a classifier on audio files to predict its genre. We work through this project on GTZAN music genre classification dataset. This tutorial explains how to extract important features from audio files. In this deep learning project we have implemented a K nearest neighbor using a count of K .

LITERATURE AND SURVEY

2.1 EXISTING SYSTEM

Classifying the music without human interaction has been a fascinating problem for lots of people working from different branches like signal processing, machine learning, and music theory. There is a vast amount of research work related to audio and music classification.

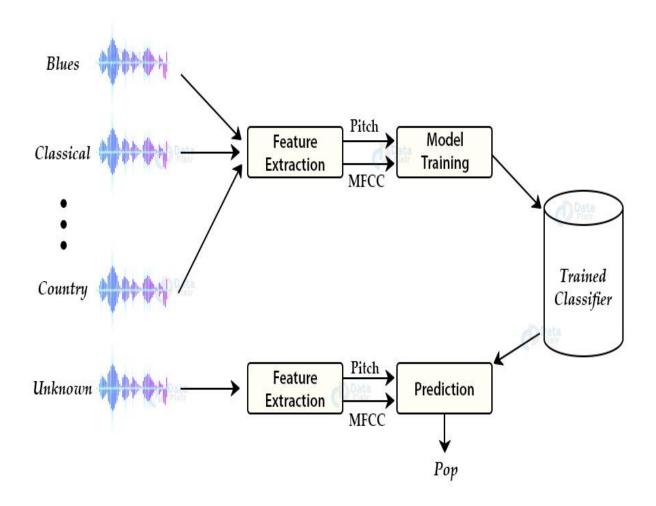

A work by Tzanetakis and Cook in (2002), where researchers performed music genre classification using the timbral-related features, texture features, and pitch-related features based on the multi-pitch detection algorithm. Some of the features used in this work include MFCCs, roll-off, and spectral contrast. Their system achieved an overall accuracy.

2.2 PROPOSED SYSTEM

In our proposed solution, we have compared the performance of several machine learning and deep learning algorithms that we have used for the task of music genre classification.

THEORETICAL ANALYSIS

3.1 BLOCK DIAGRAM

3.2 HARDWARE AND SOFTWARE DESIGNING

HARDWARE DESIGNING:

The hardware required for the development of this project is:

• Processor : Intel® CoreTM i5-9300H

• Processor speed: 2.4GHz

• RAM Size: 8 GB DDR

• System Type : X64-based processor

SOFTWARE DESIGNING:

The software required for the development of this project is:

• Desktop GUI: Anaconda Navigator

• Operating System : Windows 10(and other higher version)

• Front end : HTML,CSS,JAVASCRIPT

• Programming Language: PYTHON

• Cloud Computing Service : IBM Cloud Services

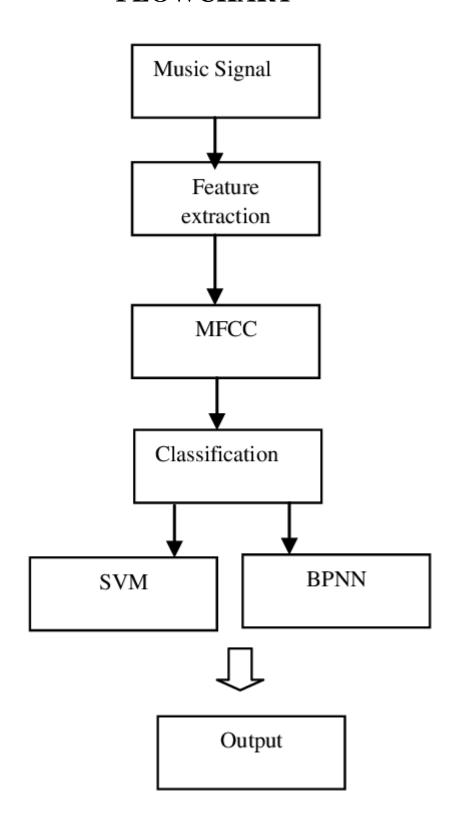

EXPERIMENTAL INVESTIGATIONS

The GTZAN genre collection dataset was collected. It consists of 1000 audio files each having 30 seconds duration. There are 10 classes (10 music genres) each containing 100 audio tracks. Each track is in .way format. It contains audio files of the following 10 genres:

- Blues
- Classical
- Country
- Disco
- Hip-hop
- Jazz
- Metal
- Pop
- Reggae
- Rock

....

FLOWCHART

RESULT

Since GTZAN data set consists of ten different genres, accuracy was used as the main performance metric. Although it can be assumed as a subjective measure in view of a listener, the average percentage of music similarity is also used as a metric for quality of music recommendation.

The best performance in terms of accuracy is observed for the KNN model that uses as an input to predict the music genre with a test accuracy of 88.54.

Although performance varied with each classification algorithm, similar trends were identified in the results of each. For example, across most experiments, Hip-Hop were classified the most accurately.

ADVANTAGES AND DISADVANTAGES

ADVANTAGES

- Music genres are important because they are a fundamental means of understanding and discussing music as an art form.
- Classification results can be used to support sociological and psychological research into how humans construct the notion of musical similarity and form musical groupings, and how this compares to the objective truth produced by computerized classifiers.
- Effective if the training data is large

DISADVANTAGES

- This method is not able to be implemented in real time since we need to process the information of whole piece of music.
- Need to determine the value of parameter K.
- Distance based on learning is not clear which type of distance to use and which attribute to use to produce the best results.

APPLICATIONS

Companies nowadays use music classification, either to be able to place recommendations to their customers (such as Spotify, Soundcloud) or simply as a product (for example, Shazam). Determining music genres is the first step in that direction. Machine Learning techniques have proved to be quite successful in extracting trends and patterns from a large data pool. The same principles are applied in Music Analysis also.

CONCLUSION AND FUTURE SCOPE

CONCLUSION

This project studies several methods of music genre classification. We study several audio feature extraction methods using digital signal processing methods, including MFCC (mel-frequency cepstral coefficients), etc. And we propose two main architectures for music genre classification. One is the combination with different level features with decision tree or random forest model, and the other one is the combination with a series of MFCC coefficients with KNN and K-Means clustering. We quantitatively compare the performance of classifying jazz, classical, metal and pop music using two architectures, and find that the random forest model gives a better result with 86.75% accuracy.

FUTURE SCOPE

In the future, we hope to experiment with other types of deep learning methods, given they performed the best. Given that this is time series data, some sort of KNN model may work. We are also curious about generative aspects of this project, including some sort of genre conversion (in the same vein as generative adversarial networks which repaint photos in the style of Van Gogh, but for specifically for music). Additionally, we suspect that we may have opportunities for transfer learning, for example in classifying music by artist or by decade.

➤ In our project, although we do the dataset augmentation by split the 30 seconds music into mutiple clips with various split segmentation intervals. But we still see some over-fitting and inconsistency in the accuracy results. More test data will absolutely help us move further and understand more deeper of the algorithms we learnt in this course
